Aortic Stenosis

Aortic stenosis (AS) is the narrowing of the aortic valve, which obstructs the blood flow from the left ventricle of the heart to the ascending aorta. Stenosis can occur because of thickening, stiffening, or fusion of the aortic valve, which prevents the valve from opening completely and limits the amount of blood flowing through the valve. Aortic stenosis can be congenital or acquired. The most common cause of aortic stenosis in the elderly is aortic sclerosis, a degenerative disease characterized by fibrosis and calcification of the aortic valve. In patients who are less than 70 years of age, the most common cause of aortic stenosis is a congenital bicuspid aortic valve. Rheumatic fever is the most common cause of aortic stenosis in developing countries. Other potential causes of aortic valve disease include autoimmune disorders, carcinoid syndrome, metabolic disorders, weight-loss medications, and radiation therapy. Individuals who have a history of infective endocarditis, myocardial infarction, or heart failure are at an increased risk of developing aortic stenosis. Other risk factors include old age, hypercholesterolemia, hypertension, diabetes, insulin resistance, obesity, smoking, and a family history of early cardiac disease.

AS is graded on a combination of hemodynamic and natural history data. According to current guidelines, severe AS is defined as an aortic valve area (AVA) <1.0 cm² (or <0.6 cm²/m² body surface area), mean aortic valve pressure gradient >40 mm Hg, or an aortic jet velocity >4 m/s. Two-dimensional transthoracic
echocardiography (TTE) is the standard for diagnosis and severity assessment through Doppler quantification of maximum jet velocity, mean transvalvular pressure gradient, and AVA by continuity equation.  

**Transcatheter aortic valve replacement**

Transcatheter pulmonary valve replacement also referred to as percutaneous or catheter-based aortic valve replacement or percutaneous aortic valve implantation, is a minimally invasive heart surgery that involves the positioning and placement of the aortic valve prosthesis via a catheter inserted into a vein. These techniques allow cardiopulmonary bypass to be avoided, and may reduce the risks of bleeding and infection.

The transcatheter procedures used to deploy and set replacement aortic valves into place can be transfemoral or transapical or, less commonly, subclavian or direct transaortic access. The transfemoral procedure involves inserting a flexible aortic valve prosthetic device into a catheter, threading the catheter up the femoral vein and into the heart, where the valve is released and set into place. The transapical procedure involves a small incision being made into the chest and then the catheter is fed through the apex (tip) of the heart where the valve is released and set into place. A balloon may be used to expand the valve while seating it into its proper position in any of the procedures. Complications of transcatheter aortic valve replacement (TAVR) include shock and low cardiac output during and following deployment, annular rupture, vascular complications, myocardial injury, heart block, paravalvular aortic regurgitation, and stroke.

The FDA classifies transcatheter aortic valve implantation (TAVI) devices as Class III under the designation “aortic valve, prosthesis, percutaneously delivered” (premarket approval [PMA] Product Code NPT). The following devices are FDA approved:

- **The Edwards SAPIEN Transcatheter Heart Valve** (Edwards Lifesciences LLC) was approved on November 2, 2011, for transfemoral delivery in patients with severe symptomatic native aortic valve stenosis. The Edwards SAPIEN XT (Edwards Lifesciences LLC) was approved on June 16, 2014, for relief of AS in patients with symptomatic heart disease due to severe native calcific AS, and with native anatomy appropriate for the 23-, 26-, or 29-mm valve system, judged by a heart team (including a cardiac surgeon) to be at high or greater risk for open surgical therapy. The Edwards SAPIEN 3 (Edwards Lifesciences LLC) received PMA on June 17, 2015, based on early data from the Placement of Aortic Transcatheter Valves II (PARTNER II) trial. The SAPIEN 3 transcatheter heart valve (Edwards Lifesciences LLC.) received expanded approval in June, 2017 and is now indicated for aortic and mitral valve-in-valve procedures in high-risk or extreme-risk candidates for a subsequent open-heart surgery to replace their failing bioprosthetic valve.

- **The Medtronic CoreValve System** (Medtronic CoreValve LLC) was approved by the FDA on March 30, 2015, for use in patients with symptomatic heart disease due to either severe native calcific AS or failure of a surgical bioprosthetic aortic valve who are judged by a heart team, including a cardiac surgeon, to be at high or greater risk for open surgical therapy (i.e., STS operative risk score 8% or at a 15% risk of mortality at 30 days).  

228
CENTERS FOR MEDICARE AND MEDICAID SERVICES (CMS) 1

The National Coverage Determination (NCD) for Transcatheter Aortic Valve Replacement (TAVR) #20.32 states that CMS covers TAVR for the treatment of symptomatic aortic valve stenosis when furnished according to an FDA approved indication and when all of the following conditions are met: 1

- Procedure is furnished with a complete aortic valve and implantation system that has received FDA premarket approval (PMA) for that system's FDA approved indication.
- Two cardiac surgeons have independently examined the patient face-to-face and evaluated the patient's suitability for open AVR surgery, both surgeons have documented the rationale for their clinical judgment, and the rationale is available to the heart team.
- Patient (preoperatively and postoperatively) is under the care of a heart team that is a cohesive, multi-disciplinary team of medical professionals; the heart team concept embodies collaboration and dedication across medical specialties to offer optimal patient-centered care.

INITIAL COVERAGE CRITERIA 3 4 5 28 29

Transcatheter aortic valve implantation using an FDA approved valve may be considered medically necessary in children and adults with aortic stenosis and may be authorized when the following criteria are met: [ALL]

- Evaluation by an experienced heart team that includes a cardiologist and/or cardiac interventionalist and two cardiothoracic surgeons who have documented that either:
  - open surgical AVR is inoperable and existing comorbidities would not preclude the expected benefit from correction of the aortic stenosis; or
  - open surgical AVR candidate with a Society of Thoracic Surgeons predicted operative risk score ≥ 8%, or are judged by the heart team to be at a ≥ 15% risk of mortality for surgical aortic valve replacement

- Diagnosis of calcific aortic valve stenosis confirmed by echocardiograph as:
  - mean gradient >40 mm Hg or jet velocity >4.0 m/s; or
  - initial Aortic Valve area (AVA) of <0.8 cm² or indexed effective orifice area (EOA) <0.5 cm²/m² within 45 days of the date of the procedure; and
  - symptomatic of aortic valve stenosis (i.e. angina, syncope, progressive exercise intolerance); and
  - NYHA functional class II or greater; and
  - Ejection fraction > 20%

COVERAGE EXCLUSIONS 3 4 5 28 29

Coverage exclusions include presence of any of the following conditions:

- Evidence of an acute myocardial infarction ≤1 month (30 days) before the intended treatment
- Aortic valve is a congenital unicuspid or congenital bicuspid valve, or is noncalcified
- Hemodynamic or respiratory instability requiring inotropic support, mechanical ventilation, or mechanical heart assistance within 30 days of screening evaluation
- Hypertrophic cardiomyopathy with or without obstruction
Severe left ventricular dysfunction with LVEF <20%
Severe pulmonary hypertension and RV dysfunction
Echocardiographic evidence of intracardiac mass, thrombus or vegetation
A known contraindication or hypersensitivity to all anticoagulation regimens, or inability to be anticoagulated for the study procedure
MRI confirmed CVA or TIA within 6 months (180 days) of the procedure
Renal insufficiency (creatinine >3.0 mg/dL) and/or end-stage renal disease requiring chronic dialysis at the time of screening
Estimated life expectancy <12 months (365 days) due to noncardiac comorbid conditions
Severe incapacitating dementia
Severe mitral regurgitation
Significant aortic disease:
  - Thoracic or abdominal aortic aneurysm (luminal diameter ≥5 cm), marked tortuosity (hyperacute bend)
  - Aortic arch atheroma (especially if >5 mm thick, protruding, or ulcerated)
  - Narrowing (especially with calcification and surface irregularities) of the abdominal or thoracic aorta
  - Marked tortuosity (hyperacute bend) of the aorta or severe “unfolding” of the thoracic aorta

### SUMMARY OF MEDICAL EVIDENCE 7-27

The preponderance of peer reviewed medical evidence for TAVI for aortic stenosis is of low to moderate in quality. There was one randomized controlled trial (RCT), but the majority of the literature regarding TAVI consists of case series. The only RCT was comprised of two cohorts of the Placement of Aortic Transcatheter Valves (PARTNER) trial. Cohort A compared TAVI with SAVR, 7 8 9 and cohort B compared TAVI with standard medical management. 10 11 A sixth study examined vascular complications that occurred following TAVI in both cohorts. 12 In both cohorts, TAVI was performed using the Edwards SAPIEN system. In cohort A, there were no differences in mortality and symptoms between patients in the TAVI and SAVR groups at any time points, with the exception of NYHA class, which showed greater improvement in the TAVI group at 30-days post-intervention. At one month following surgery, QOL in the patients receiving TAVI via the transfemoral route was significantly improved relative to the SAVR group; however, this difference disappeared by the 6-month follow-up. 9 In cohort B, TAVI was associated with a significant reduction in mortality and improvement of symptoms at 1 and 2 years after intervention, compared with standard treatment. At 2 years, patients in the TAVI group had significantly more days alive and out of the hospital compared with patients in the medical management group. Five year outcomes showed that TAVR is more beneficial than standard treatment for treatment of inoperable aortic stenosis. TAVR should be strongly considered for patients who are not surgical candidates for aortic valve replacement to improve their survival and functional status. 19

### Professional Organizations 3-6

2017 ACC Expert Consensus Decision Pathway for Transcatheter Aortic Valve Replacement in the Management of Adults with Aortic Stenosis: Continues to build on the recommendations found in the 2014
ACC/American Heart Association Guidelines for Management of Patients with Valvular Heart Disease. This document focuses on treatment of native valve aortic stenosis; it does not address “valve-in-valve” procedures and includes point-of-care checklists for the following: TAVR patient selection and evaluation, TAVR imaging assessment, TAVR procedure (key issues and considerations in performing the procedure and managing complications), and post-TAVR clinical management.  

2014 AHA/ACC Guideline for the Management of Patients with Valvular Heart Disease: Specific recommendations for the use of TAVI include that a heart team, consisting of an integrated, multidisciplinary group of healthcare professionals with expertise in valvular heart diseases, cardiac imaging, interventional cardiology, cardiac anesthesia, and cardiac surgery, should collaborate to provide optimum care. TAVI is recommended for patients who meet an indication for SAVR with prohibitive risk for SAVR and postoperative survival > 12 months. TAVI is a reasonable alternative to SAVR in patients at high surgical risk. TAVI is not recommended for patients with comorbidities that preclude the benefit from correction of AS.  

Society for Cardiovascular Angiography and Interventions (SCAI), American Association for Thoracic Surgery (AATS), American College of Cardiology Foundation (ACCF), Society of Thoracic Surgeons (STS): In a joint expert consensus statement the SCAI, AATS, ACCF, and STS indicate that transcatheter aortic valve replacement (TAVR) is recommended in patients with severe, symptomatic, calcific stenosis of a trileaflet aortic valve who have aortic and vascular anatomy suitable for TAVR and a predicted survival >12 months, and who have a prohibitive surgical risk as defined by an estimated 50% or greater risk of mortality or irreversible morbidity at 30 days or other factors such as frailty, prior radiation therapy, porcelain aorta, and severe hepatic or pulmonary disease.
